

The module you want to convert to a groovy module can not be already installed as a project before the groovy plugins were installed. If you had the project already running, remove it complete again (also within file system), close Eclipse, and import it again. I had the problem that after converting the module to a groovy module, the module did never appear within the Webapp's 'Web App Libraries'. Make sure that after importing it again it shows up within your Webapp module in the 'Web App Libraries'.

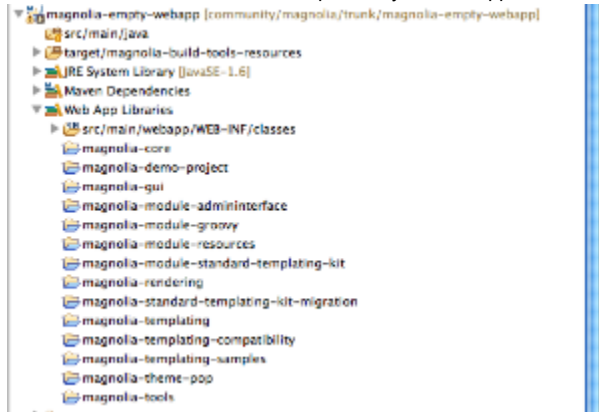

Now convert the module to a Groovy module.

After converting it will look like this:

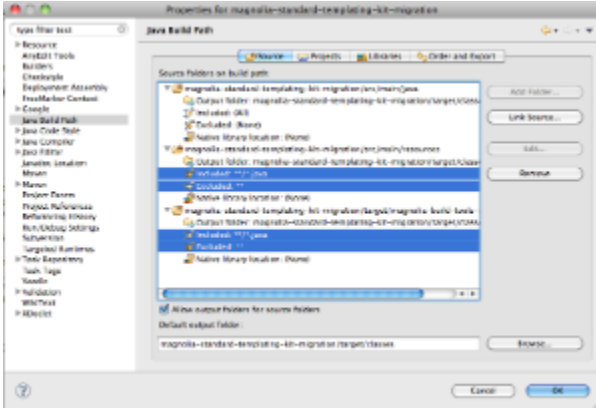

Make sure the module still shows up within your Webapp module in the 'Web App Libraries'.

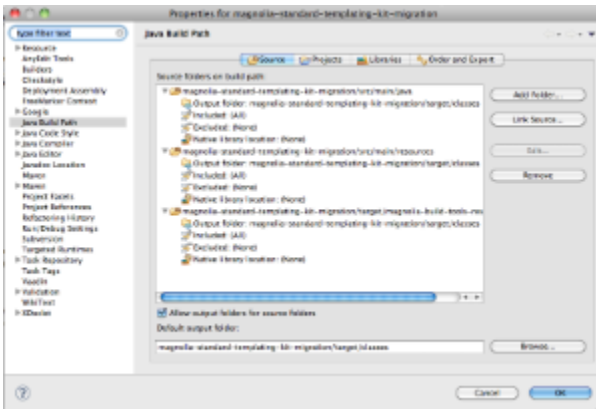

Remove excludes and includes from Java build path

Go into the project properties, and remove from the 'Java Build path' -> 'source' all excludes and includes.

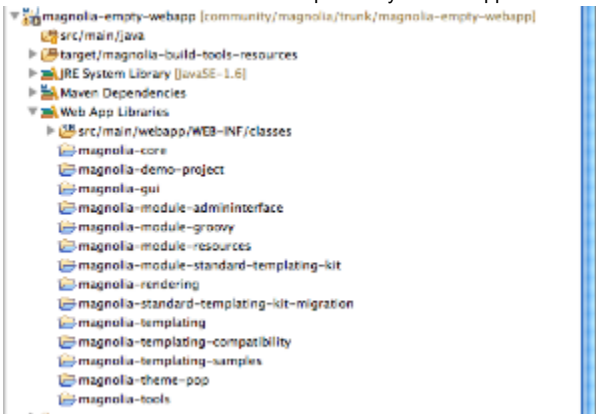

Result:

⚠ Attention: Seems that these excludes are removed from eclipse sometimes. I suspect the 'Maven -> Update Project Configuration'. It appears by that no Java class which is deprecated is not crossed anymore (as Content for example). Just remove them again... (I hope not again, and again...)

Make sure the module still shows up within your Webapp module in the 'Web App Libraries'.

Now you should be able to use the 'refactor' option in a groovy script. If you can refactor, everything went right.
